

CMT802XNXL High-Speed, Dual-Channel Digital Isolator

1 Features

- Safety-related certifications
 - DIN VDE V 0884-11: 2017-01
 - UL 1577 component recognition program
 - CSA certification according to IEC 60950-1, IEC 62368-1, IEC 61010-1 and IEC 60601-1 end equipment standards
 - CQC approval per GB4943.1-2022
 - TUV certification according to EN 60950-1, EN 62368-1 and EN 61010-1
- Robust electromagnetic compatibility
 - System-level ESD, EFT, and surge immunity
 - ± 8 kV IEC 61000-4-2 contact discharge protection across isolation barrier
 - Low emissions
- Data rate: up to 10 Mbps
- Wide supply range: 2.5 to 5.5 V
- Operation temperature: -40°C to 125°C
- Robust isolation barrier
 - More than 40-year projected lifetime
 - Up to 3.75 kV_{RMS} isolation rating
 - Up to 5.3 kV surge capability
 - ± 200 kV/ μs typical CMTI
- Default output high or low options
- Low power consumption, typical 1.5 mA per channel at 1 Mbps
- Low propagation delay: 9 ns typical (5V supplies)
- SOIC 8 package (narrow body)

2 Applications

- Industrial automatic control
- New energy vehicles
- Solar inverters
- Motor control
- Isolated SPI
- General purpose multichannel isolation

3 Description

The CMT802XNXL series devices are high-performance, dual channel digital isolators with as high as 3.75 kV_{rms} isolation voltage by means of silicon-dioxide (SiO₂) insulation barrier.

The digital isolator is used to communicate between two different power supply domains while prevents noise currents on a data bus or other circuits from entering the local ground and interfering with or damaging sensitive circuitry.

This device comes with enable pins that can be used to put the respective outputs in high impedance for multi-master driving applications and to reduce power consumption. The CMT802XNXL device has four forward and up to two reverse-direction channels. If the input power or signal is lost, the default output is high for the CMT802XN1L device and low for the CMT802XN0L device. See the Device Functional Modes section for further details.

The isolator provides high electromagnetic immunity and low emissions at low-power consumption. Through innovative chip design and layout techniques, electromagnetic compatibility of the CMT802XNXL device has been significantly enhanced to ease system-level ESD, EFT, surge, and emissions compliance.

The CMT802XNXL series device is available in narrow-body (NB) 8-pin SOIC package.

Notes:

- [1]. Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.
- [2]. All voltage values except differential I/O bus voltages are with respect to the local ground terminal (GND1 or GND2) and are peak voltage values.

8.1 Typical Application Schematic

Figure 7. Typical Application Schematic (Take the CMT8021NXL as an example)

Note: users should be careful not to connect ground and VDD reversely

8.2 PCB Layout Guidelines

The CMT802XNXL requires a 0.1 µF bypass capacitor in both input side and output side. The capacitor should be placed as close as possible to the package pin of VDD1 and VDD2 respectively. The figures below show the recommended PCB layout. Please make sure the space under the chip keeps free from planes, traces, pads and via. To enhance the robustness of design, users may also include resistors (50 ~ 300 Ω) in series with the inputs and outputs if the system is excessively noisy. The series resistors also improve the system reliability such as latch-up immunity.

The typical output impedance of an isolator driver channel is approximately $50\ \Omega \pm 40\%$. When driving loads where transmission line effects will be a factor, output pins should be appropriately terminated with controlled impedance PCB traces.

Figure 8. Recommended PCB Layout

9 Parameter Measurement Circuit Setup

Figure 9. Switching Characteristics Test Circuit and Voltage Waveforms

Notes:

1. The input pulse is supplied by a generator V_{IN} having the following characteristics: $f_{PULSE} \leq 100$ kHz, 50% duty cycle, $t_r \leq 3$ ns, $t_f \leq 3$ ns, $Z_O = 50 \Omega$. At the input, 50Ω resistor is required to terminate input generator signal. It is not needed in actual application.
2. Load capacitance influences the measurement results quite a lot, including instrumentation and fixture capacitance, totally no more than 15 pF loading is preferred.

Figure 10. Common-Mode Transient Immunity Test Circuit

Notes:

1. $C_L = 15$ pF, the total instrumentation and connection is within $\pm 20\%$.

Notes:

- [1]. Creepage and clearance requirements should be applied according to the specific equipment isolation standards of an application. Care should be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed-circuit board do not reduce this distance. Creepage and clearance on a printed-circuit board become equal in certain cases. Techniques such as inserting grooves and/or ribs on a printed-circuit board are used to help increase these specifications.
- [2]. This coupler is suitable for safe electrical insulation only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- [3]. Testing is carried out in air or oil to determine the intrinsic surge immunity of the isolation barrier.
- [4]. Apparent charge is electrical discharge caused by a partial discharge (pd).
- [5]. All pins on each side of the barrier are tied together creating a two-terminal device.

10.8 Safety Limiting Values

Safety limiting intends to minimize potential damage to the isolation barrier upon failure of input or output circuitry. A failure of the I/O can allow low resistance to ground or the supply and, without current limiting, dissipate sufficient power to overheat the die and damage the isolation barrier potentially leading to secondary system failures

11 Function Description

11.1 Function Overview

The CMT802XNXL device is a high-performance, quad-channel digital isolator with 3750 V_{RMS} isolation rating. The CMT802XNXL has an On-Off keying (OOK) modulation scheme to transmit the digital data across a silicon dioxide based isolation barrier. The transmitter sends a high-frequency carrier across the barrier to represent one digital state and sends no signal to represent the other digital state. The receiver demodulates the signal after advanced signal conditioning and produces the output through a buffer stage. If the ENx pin is low then the output goes to high impedance. The CMT802XNXL also incorporates advanced circuit techniques to maximize the CMT1 performance and minimize the radiated emissions due to the high frequency carrier and IO buffer switching. The figure below shows a conceptual detail of how the On-Off keying scheme works.

11.2 Functional Modes

The table below lists the functional modes of the CMT802XNXL.

Table 16. Function Table^[1]

V _{DD1}	V _{DD2}	Input (IN _x) ^[2]	Output (OUT _x)	Comment
PU	PU	H	H	Normal operation: A channel output assumes the logic state of its input
		L	L	
		Open	Default	Default mode: when IN _x is open, the corresponding channel output goes to its default logic state
PD	PU	X	Default	Default mode: when V _{DD1} is unpowered, a channel output assumes the logic state based on the selected default option. When V _{DD1} transitions from unpowered to powered-up, a channel output assumes the logic state of the input. When V _{DD1} transitions from powered-up to unpowered, channel output assumes the selected default state
X	PD	X	Undetermined	When V _{DD2} is unpowered, a channel output is undetermined ^[3] . When V _{DD2} transitions from unpowered to powered-up, a channel output assumes the logic state of the input

11.3 Insulation Lifetime

Insulation lifetime projection data is collected by using industry-standard Time Dependent Dielectric Breakdown (TDDB) test method. In this test, all pins on each side of the barrier are tied together creating a two-terminal device and high voltage applied between the two sides; See the figure below for TDDB test setup. The insulation breakdown data is collected at various high voltages switching at 60 Hz over temperature. For reinforced insulation, VDE standard requires the use of TDDB projection line

with failure rate of less than 1 part per million (ppm). Even though the expected minimum insulation lifetime is 20 years at the specified working isolation voltage, VDE reinforced certification requires additional safety margin of 20% for working voltage and 87.5% for lifetime which translates into minimum required insulation lifetime of 37.5 years at a working voltage that's 20% higher than the specified value.
